Path Analysis Spss

path analysis involves the analysis and comparison of two models - a "full model" with all of the possible paths included and a "reduced model" which has some of the paths deleted, because they are hypothesized to not contribute to the model.

Example of Path Analysis via Regression using SPSS

Path analysis in SPSS is described as a statistical technique primarily used to investigate the comparative strength of indirect and direct variable relationships. It is also a candid multiple regression extension that aims to give magnitude estimates and hypothesized casual connections significance between variable sets.

Path analysis was developed by Sewall Wright, a geneticist, in 1918. Over time the method has been adopted in other physical sciences and social sciences, including sociology. Today one can conduct path analysis with statistical programs including SPSS and STATA, among others. The method is also known as causal modeling, analysis of covariance structures, and latent variable models.

Path analysis is a graphical representation of multiple regression models. In this analysis, the graphs represent the relationship between the dependent and independent variables with the help of square and arrows. These graphs show the causation between different variables of a regression model. To conduct a path analysis, simply write the names of variables in square boxes and connect the square boxes with arrows.

Path analysis is a type of statistical method to investigate the direct and indirect relationship among a set of exogenous (independent, predictor, input) and endogenous (dependent, output) variables. Path analysis can be viewed as generalization of regression and mediation analysis where multiple input, mediators, and output can be used.
